The object is a hollow ball with a short and narrow circular tube in the side. The wall of the tube is made of soft material so that it is stronger than the ball. Now, my question is: How do I "squeeze" a ball through a pipe, with the constraint that the aperture is quite large and the wall of the tube can be flexible (in other words, it is soft and large enough to allow the ball to pass through even if it were relaxed)? Obviously, the ball must be small enough so that it would compress to a small size even without the tube wall. The exact dimension of the ball is not important to my question. However, the tube needs to be soft to allow easy passage of the ball. I thought of following approach: The tube wall is made flexible and springs when squeezed. However, this is more of an engineering problem and I am not aware if such a structure exists. My questions are: If I remove the "squeezing" constraint and allow the tube wall to be "unstressed", what would happen to the ball? In other words, how would a flexible

The present invention relates to a new and distinctive soybean variety, designated XB07H12 which has been the result of years of careful breeding and selection as part of a soybean breeding program. There are numerous steps in the development of any novel, desirable plant germplasm. Plant breeding begins with the analysis and definition of problems and weaknesses of the current germplasm, the establishment of program goals, and the definition of specific breeding objectives. The next step is selection of germplasm that possess the traits to meet the program goals. The goal is to combine in a single variety an improved combination of desirable traits from the parental germplasm. These important traits may include but are not limited to higher seed yield, resistance to diseases and insects, tolerance to drought and heat, and better agronomic qualities. These processes, which lead to the final step of marketing and distribution, can take from six to twelve years from the time the first cross is made. Therefore, development of new varieties is a time-consuming process that requires precise forward planning, efficient use of resources, and a minimum of changes in direction. Soybean (*Glycine max*), is an important and valuable field crop. Thus, a continuing goal of soybean breeders is to develop stable, high yielding soybean varieties that are agronomically sound. The reasons for this goal are to maximize the amount of grain produced on the land used and to supply food for both animals and humans. To accomplish this goal, the soybean breeder must select and develop soybean plants that have the traits that result in superior varieties. Pioneer soybean research staff create over 500,000 potential new varieties each year. Of those new varieties, less than 50 and more commonly
